## 1. Overview

This codebook describes the Global Resources Dataset.

# 2. Coding Process

The unit of observation is the mine, resource extraction site, or resource processing facility in each year. The data are coded from annual country fact sheets produced by the United States Geological Survey (USGS) website.

We undertook a number of safeguards to ensure high quality data. First, we undertook an initial round of coding. Next, especially since geolocations are not always clear with higher level precision codes, we undertook a second round of coding to check all of the entries for accuracy. At the end of the second round of coding, the coders randomly sampled each other's work and performed some triple-checks. In the third round of coding, coders performed an initial coding of each location-year, with another coder double-checking over each coded entry. Senior coders also performed spot checks throughout and adjudicated all difficult cases that were not initially clear from the PDF documents produced by the United States Geological Survey (USGS). After the second and third rounds of coding, we further examined instances in which the same location was given different latitudes and longitudes for different location-years. Accordingly, an expert coder then re-checked those locations and assigned a final latitude and longitude to them ex post.

# 3. Frequently Asked Questions

1. Did you perform any interpolation or imputation, and can you explain the coding gaps?

No, we did not do any interpolation or imputation. First, most yearly USGS country reports tend to be written by the same author or set of authors every year. Essentially, there does not appear to be much staff turnover over time for the authors of

these country reports. Accordingly, it stands to reason that the USGS country experts would not remove observations from year-to-year without a reason. Second, civil wars and natural disasters, for example, could affect mine output levels, so we would not recommend that users perform any sort of interpolation without specific knowledge of the country-years in question. Where interpolation/imputation could be germane is if the observations refer to contiguous gaps in USGS country reports. Users can discern whether there are contiguous gaps for a particular country by referring to Table D2. By the same token, we would still advise each user who is considering interpolation/imputation to analyse the specific country-years in question. For example, it is possible that there is a coding gap due to a civil war or natural disaster, in which case the gap might be justifiable. On our end, we endeavored to ensure that all coding gaps were a result of there not being a USGS country report available for a particular country-year. In other words, once we started coding a country, we did not stop until there were no more USGS reports available.

2. I noticed that the GRD only goes until 2014 or 2015 for most countries. Others countries only extend until 2012 or 2013. Still others have uncoded country reports for years prior to 2002. Why is that the case?

We coded as many years as possible for each country. Thus far, 88 different coders have contributed to the GRD. Given the enormous coding task posed by the sheer number of countries in the GRD and the non-uniform release of newer reports for each country, the newer years are inevitably the ones for which the GRD is least likely to cover. Pending resource availability, we may extend the GRD to cover some earlier and later country-years for which USGS country reports are available. Additionally, we may extend the GRD to new countries.

3. How do you distinguish between pure minerals/concentrates and ores?

The extent to which USGS country reports distinguish between pure minerals/concentrates and ores is extremely limited in our large dataset. More broadly, simply because USGS

reports output of a certain quantity of units at a given mine in each year does not necessarily mean that all of those units are pure minerals/concentrates. Many minerals contain significant impurities, especially when they are mined from the ground and caves. In any case, the extent to which the minerals reported will also contain impurities is not something that we—or even USGS—can realistically know: impurity levels will differ by mineral, country, and mine; and USGS does not individually inspect the output of each mine. Against this backdrop, we decided to sum the outputs of ores and concentrates in the few instances when the USGS reports them separately for a given mine. At one point, we considered dropping the ores from output, but the ores are clearly worth some portion of the pure minerals/concentrates, even if they are reported separately in some cases. Additionally, the prices of ores are only available for a few different minerals, so we generally have no choice to combine ores and concentrates. Otherwise, we cannot put a value on the mine or extraction site for the ores. In the limited instances when we summed the output of ores and concentrates, there may be some concern of potential mine value inflation. However, following our Journal of Conflict Resolution article and the broader literature, any such value inflation can be minimized by taking the log of each mine/site's value.

## 4. Variables

This section outlines the variables in the dataset.

#### 4.1. resource

This information is taken from United States Geological Survey (USGS). Details on the individuals resources covered in this dataset are found in Table D1. In total, there are 192 different resources in the dataset.

Table D1: Resources in the Global Resources Dataset (GRD)

Resource	Number of Observations
alumina	674
aluminum	1,614
aluminum floride	11
amazonite	2
amber	7
amethyst	21
ametrine	7
ammonia	198
ammonium nitrate	1
andalusite	65
anhydrite	14
antimony	386

# 4.2. country

This variable identifies the country in which a resource-location-year observation is located. Table D2 lists the countries included in the GRD, the first and last year for which data is included, and the total number of resource location-years for each country. The

number in parentheses after the country name indicates the number of years for which data are missing. In most cases, this is because there is no USGS country report for that year. Most missing observations occur before 2004.

Table D2: Country-Years in the Global Resources Dataset

Country	Beginning Year	Ending Year	Observations
Afghanistan	2008	2015	163

Table D2: Country-Years in the Global Resources Dataset – continued

Country	Beginning Year	Ending Year	Observations
Zimbabwe (7)	1998	2015	903

### 4.3. year

This variable corresponds to the year of the respective resource value. This information is taken from United States Geological Survey (USGS). Years range from 1994–2015. Data availability varies by country. Details on the individuals country-years covered in this dataset can be found in Table D2.

#### 4.4. COW\_code

This variable corresponds to the Correlates of War (COW) country code.

## 4.5. gwno

This variable corresponds to the Gleditsch-Ward country code.

#### 4.6. wb\_ccode

This variable corresponds to the World Bank/ISO3 country code.

# 4.7. region\_wb

This variable corresponds to World Bank region of the mine location or resource extraction site. There are five regions in the dataset: (Subsaharan) Africa; Middle East and North Africa; Latin America and Caribbean; South Asia; and East Asia and Pacific.

#### 4.8. continent

This variable corresponds to the continent of the mine location or resource extraction site. The dataset contains observations from Asia; Europe; the Americas (South and Central America); and Africa.

### 4.9. gid

This variable corresponds to the grid-cell ID from the PRIO-GRID (see Tollefsen, Strand and Buhaug, 2012). In line with Tollefsen, Strand and Buhaug (2012), we performed the relevant spatial join with the WGS84 coordinate reference system, using the sf package in R (Pebesma, 2018).

### 4.10. gid\_centroid\_latitude

This variable corresponds to the latitude of the grid-cell centroid from the PRIO-GRID. In line with Tollefsen, Strand and Buhaug (2012), we performed the relevant spatial join with the WGS84 coordinate reference system

# 4.11. gid\_centroid\_longitude

This variable corresponds to the longitude of the grid-cell centroid from the PRIO-GRID. In line with Tollefsen, Strand and Buhaug (2012), we performed the relevant spatial join with the WGS84 coordinate reference system.

#### 4.12. standard\_measure

This variable identifies the standard unit of measure for each resource. Information is taken from United States Geological Survey (USGS). Data are recorded using the following units: 42-gallon barrels, 42-gallon barrels per day, billion cubic meters, carats, cubic meters, kilograms, metric tons, metric tons per day, million 42-gallon barrels, million bricks, million cubic meters, million cubic meters per day, million metric tons, square meters, thousand

41-gallon barrels, thousand 41-gallon barrels, thousand 42-gallon barrels per day, thousand 42-gallon barrels per day, thousand bricks, thousand carats, thousand cubic meters, thousand metric tons, and thousand square meters.

#### 4.13. comtrade\_unit

This information is taken from UN Comtrade. It describes the unit measure for the respective UN Comtrade prices. Prices are expressed in carats, cubic meters, kilograms, and liters.

#### 4.14. wb\_unit

This information is taken from the World Bank's Global Economic Monitor. The variable describes the unit corresponding to the world price of the respective mineral or resource. Prices are expressed in 42-gallon barrels, metric tons, troy ounces, and mmbtu.

## 4.15. usgs\_unit

This information is taken from the United States Geological Survey (USGS). The variable describes the unit corresponding to the US prices of the respective mineral or resource. Prices are expressed in metric tons.

### 4.16. multicolour\_unit

This is information is taken from Multicolour. The variable describes the unit corresponding to the world price of the respective mineral or resource. All Multicolour prices are given in carats. For more inquiries on Multicolour prices, please contact David Weinberg at Multicolour: info@multicolour.com.

| API Gravity Measure | Corresponding Density (kg/m³) | 20 | 933.993 | 25 | 904.152 | 30 | 876.161 | 35 | 849.850 | 40 | 825.073 | 45 | 800.8 |

Table D3: API Gravity to Density Conversions

#### 4.17. APIforoil

This information refers to the American Petroleum Institute (API) gravity measure for oil/petroleum or products thereof. It is the industry standard for expressing density, as compared to the density of water. Higher API gravities entail lower densities, which in turn return higher prices on commodity spot markets. When oil has a lower API gravity/higher density, yielding a heavier 42-gallon oil barrel/drum, it requires additional processing steps to make the oil usable.

Table D3 provides the densities in kg/m³ corresponding to the API gravity measures for a sample of API gravities used in this dataset. The data availability for API gravity based on oil field assays is limited. Thus, when we were unable to find the API gravity each oil field, we approximated the API gravities by country based on information here, here, here, here, other websites, and:

Awadh, Salih Muhammed, and HebaSadoon Al-Mimar. 2013. "Statistical Analysis of the Relations between API, Specific Gravity, and Sulfur Content in the Universal Crude Oil." *International Journal of Science and Research* 4(5): 1279-1284.

#### 4.18. SGforoil

This variable pertains to the specific gravity of oil/petroleum and products thereof.

The specific gravity can be calculated as follows:

### 4.19. density

This information refers to the density of variables for which output data is expressed in terms of mass but price data is given in volume or heat content—or vice-versa. Table D4 provides the relevant densities (kg/m³) used in this dataset. Note that densities are only relevant when converting between mass, volume, or heat content units.

**Corresponding Density** Resource  $(kg/m^3)$ clay (bricks) 1900 gasoline 719.7granite 2075 helium 147 limestone 2360 liquefied petroleum gas 550 liquefied natural gas 450 marble 2700 natural gas 0.8oil see Table D3 1025 salt stone 2515

Table D4: Density by Resource

#### 4.20. heat\_content

This variable describes the heat content of certain resources in MMBtu/bbl. Refer to Table D5 for the resource for which it was necessary to have heat content information due to conversions between mass, volume, and heat content units. Heat contents by resource can be found on the website of the Society for Petroleum Engineers.

# 4.21. specific\_surface\_area

This variable corresponds to the specific surface area of stone, sandstone, granite, and marble in meters<sup>2</sup>/grams. This variable is necessary for these minerals because USGS annual

Resource	Heat Content (MMBtu/bbl)
liquified natural gas	3.735
natural gas	3.735
oil/petroleum	5.8
petrochemicals	5.976
petroleum products	5.976

Table D5: Heat Content by Resource

allocation capacity figures are expressed in square meters. We obtained data from the following resources:

- Keppert, Martin, Jaromir Zumar, Monika Cachova, Dana Konakova, Petr Svora, Zbysek Pavlik, Eva Vejmelkova, and Robert Cerny. 2016. "Water Vapor Diffusion and Adsorption of Sandstones." Advances in Materials Science and Engineering (2016). DOI:10.1155/2016/8039748
- Ticknor, Kenneth V., and Preet P.S. Saluja. 1990. "Determination of Surface Areas of Mineral Powders By Adsorption Capacity" Clays and Clay Minerals (38)4: 437-441.

#### 4.22. locationname

This information is taken from United States Geological Survey (USGS). The location information describes the closest available city, town, or point of interest to the mine or resource extraction site.

# 4.23. mineownership

This information comes from United States Geological Survey (USGS). The following different types of mines are available in the data: artisanal, artisanal/military, cooperative, cooperative/industrial, industrial, industrial/government, and government. When ownership information is not available, it has been listed as "n/a". The mixed categories with more than one type of owner are for instances in which there is more than one owner and neither owns a majority stake (i.e. greater than 50%). When any one of the above owns more than

a 50% stake, it is classified as only one of the above categories.

### 4.24. minetype

This variable denotes whether the site is a mine, other extraction site, refinery, or downstream plant/processing facility. Coders consulted a variety of sources to determine the minetype, including the USGS country reports, Internet searches, specialized publications, and remote sensing images of the location.

We define these values as follows:

- 1. Mines are generally related to ores and minerals. They can be underground, or aboveground in the case of strip-mining.
- 2. Extraction sites cover a broader scope, and includes gas and oil. This minetype value also river deposits of commodities such as diamonds or gold.
- 3. Production facilities are locations which smelt or produce a commodity, rather than extract it. Cement and steel are examples, as well as anything specified as a "metal" or a product of some process.
- 4. Refineries are generally only put as a minetype if it is specifically referred to as such in the USGS .pdf. An example of this would be "Petroleum: Refined", rather than the usual "Petroleum" or "Petroleum: Crude". We apply the same process to metals.
  - 5. The Unknown minetype exists in the event that no minetype can be identified.

#### 4.25. admin1

This information is taken from GeoNames (www.geonames.org) or Google Maps on the basis of the location name from USGS. This information corresponds to the administrative level 1 precision code. Generally, it corresponds to a province/department/state.

#### 4.26. admin2

This information is taken from GeoNames (www.geonames.org) or Google Maps on the basis of the location name from USGS. This information corresponds to the administrative level 2 precision code. Generally, it corresponds to a district/municipality.

#### 4.27. latitude

This information is taken from GeoNames (www.geonames.org) or Google Maps on the basis of the location name from USGS. In instances where there are multiple location names that match the USGS description, the coder arbitrates between the locations given clues on the USGS document, such as province information given by USGS. Further, geonames provides aerial shots of the location, which can be used to pinpoint a probable mine location.

### 4.28. longtitude

This information is taken from GeoNames (www.geonames.org) or Google Maps on the basis of the location name from USGS. In instances where there are multiple location names that match the USGS description, the coder arbitrates between the locations given clues on the USGS document, such as province information given by USGS. Further, geonames provides aerial shots of the location, which can be used to pinpoint a probable mine location.

# 4.29. precisioncode

This information is derived from GeoNames (www.geonames.org) or Google Maps on the basis of the location name from USGS. We use the following precision codes:

- 1: Mine/production facility itself
- 2: Nearby city
- 3: District level
- 4: Province

#### • 9: Unsure if location is correct

### 4.30. comtrade\_price\_mult

This variables corresponds to the UN Comtrade export price of the resource, expressed in its standard measure output unit (see above). Thus, prices are available for specific resources and years but also each respective country. All prices are deflated to represent their 2010 United States dollar value. To access the deflators, refer to the World Bank's World Development Indicators.

### 4.31. wb\_price\_mult

This variables corresponds to the World Bank price for the resource, expressed in its standard measure unit (see above). All prices, which are world prices, are deflated to represent their 2010 United States dollar value. To access the deflators, refer to the World Bank's World Development Indicators.

# 4.32. usgs\_price\_mult

This variables corresponds to the USGS for the resource, expressed in its standard measure unit (see above). All prices, which are world prices, are deflated to represent their 2010 United States dollar value. To access the deflators, refer to the World Bank's World Development Indicators.

Kindly also note the following:

- 1. We merge antimony and antimony ore into one antimony price variable. There are few antimony ore observations in our dataset, and pure antimony is a very rare in occurrence. So, it is logical to use one price for antimony.
- 2. We merge boron and boron refined concentrates into one boron price. There are few boron observations in the dataset.

## 4.33. multicolour\_price\_mult

This variable corresponds to the Multicolour price for the resource, expressed in its standard measure unit. All prices, which are world prices, are deflated to represent their 2010 United States dollar value. To access the deflators, refer to the World Bank's World Development Indicators. For all information regarding Multicolour, please contact David Weinberg: info@multicolour.com

Kindly also note the following:

- 1. We merge bi-color tourmaline with chrome tourmaline into one tourmaline price. Often, it is possible to find tourmalines of different colors in the same mines.
- 2. We merge color change sapphire, fancy sapphire, and sapphire into one sapphire price. It is possible to find sapphires of different colors in the same mine.
- 3. We merge grossular garnet, tsavorite, color change garnet, and garnet into one garnet price. Garnets of different colors can be found in the same mine.
- 4. We merge chrysocolla quartz, rose quartz, rutilated quartz, and quartz into one quartz price.

# 4.34. multiplier\_comtrade

This variable corresponds to the multiplier used for the conversion of the UN Comtrade price unit conversion into the standard measure unit.

# 4.35. multiplier\_wb

This variable corresponds to the multiplier used for the conversion of the World Bank price unit conversion into the standard measure unit.

### 4.36. multiplier\_usgs

This variable corresponds to the multiplier used for the conversion of the United States Geological Service (USGS) price unit conversion into the standard measure unit.

## 4.37. multiplier\_multicolour

This variable corresponds to the multiplier used for the conversion of the USGS or World Bank price unit conversion into the standard measure unit.

### 4.38. annual allocation capacity

This information is taken from United States Geological Survey (USGS). It measures yearly output of the mine or resource extraction site in the standard measure unit.

### 4.39. exp\_annual\_value\_location1

This variable accounts for annual value of the location in 2010 United States Dollars (USD). This measure of the annual value of the location prioritizes UN Comtrade export prices first. Then, it incorporates prices from the World Bank, followed by those of the USGS. The variable excludes prices from Multicolour.

A few reasons underpin our rationale provide one set of prices without Multicolour values. First, not each resource-year in the Multicolour dataset has a high number of observations. Second, Multicolour sales tend to be a on a very small scale, with typical prices being at the gram or carat level. Accordingly, small fluctuations in the Multicolour prices per carat, which is normal given factors such as gem quality size, clarity, and color, can make a significant difference in the price. By contrast, the prices for most minerals from UN Comtrade, USGS, the World Bank tend to be aggregated at the kilogram, metric ton, or thousand metric ton levels, making them less prone changes from small fluctuations.

### 4.40. exp\_annual\_value\_location2

This variable accounts for annual value of the location in 2010 United States Dollars (USD). This measure of the annual value of the location prioritizes UN Comtrade export prices first. Then, it incorporates world prices from World Bank, USGS, and Multicolour (in that order).

#### 4.41. wd\_annual\_value\_location1

This variable accounts for annual value of the location in 2010 United States Dollars (USD). This measure of the annual value of the location prioritizes world prices from World Bank. Then, it incorporates US prices from USGS, followed by country-specific export prices from UN Comtrade. The variable excludes prices from Multicolour.

A few reasons underpin our rationale provide one set of prices without Multicolour values. First, not each resource-year in the Multicolour dataset has a high number of observations. Second, Multicolour sales tend to be a on a very small scale, with typical prices being at the gram or carat level. Accordingly, small fluctuations in the Multicolour prices per gram or carat, which is normal given factors such as gem quality size, clarity, and color, can make a significant difference in the price. By contrast, the prices for most minerals from UN Comtrade, USGS, the World Bank tend to be aggregated at the kilogram, metric ton, or thousand metric ton levels, making them less prone to changes from small fluctuations.

#### 4.42. wd\_annual\_value\_location2

This variable accounts for annual value of the location in 2010 United States Dollars (USD). This measure of the annual value of the location prioritizes world prices from World Bank and US prices from USGS. Then, it incorporates export prices from UN Comtrade. The variables excludes prices from Multicolour.

#### 4.43. comtrade\_value

This variable corresponds to the annual value of the location using only export prices from UN comtrade.

#### 4.44. wb\_value

This variable corresponds to the annual value of the location using only world prices from the World Bank's Global Economic Monitor Commodities Pink Sheet.

### 4.45. usgs\_value

This variable corresponds to the annual value of the location using only US prices from the United States Geological Survey (USGS).

### 4.46. world\_val\_nomc

This variable corresponds to the the annual value of the location using world prices from the World Bank or US prices from USGS (in that order), excluding world prices from Multicolour. We include USGS prices alongside World Bank ones since, based our data, wb\_value and usgs\_value correlate at 0.99. That is even before logging the data, too.

### 4.47. world\_val\_withmc

This variable corresponds to the the annual value of the location using world prices from the World Bank, US prices from USGS or world prices from Multicolour (in that order). We include USGS prices alongside World Bank ones since, based our data, wb\_value and usgs\_value correlate at 0.99. That is even before logging the data, too.

#### 4.48. lootable

This is a dummy variable indicating, based on our research, that the resource is potentially lootable. To be lootable, a resource must have high value and low barriers to entry/extraction. We say "potentially" lootable because certain types of resources can be found in different extraction sites, and some of these extraction sites make it easier to extract than others. For example, gold may be mined through placer techniques, which can be done by most anyone. By the same token, gold can also be mined through the use of expensive dredging or digging machinery. Even though not everyone has access to the expensive machinery, the fact that almost anyone can mine gold through placer techniques makes the resource "lootable" for the purposes of this dataset.

# 5. Resource Price Data Availability

Table E6 provides the availability of prices used in this dataset by resource. In cases when there are prices from more than one source by variable, refer to Section 4 for how we calculate the respective prices.

Table E6: Source of Resource Prices

	UN Comtrade	World Bank	USGS	Multicolour
alumina	X		X	
aluminum	X	X	X	
aluminum floride	X			
amazonite				
amber

# 8. Contributors

We are greatly indebted to the multitude of coders who made this project possible. At the University of Texas at Austin's Innovations for Peace and Development research lab, the following graduate research fellows and research affiliates contributed to the data collection: Nicole Pownall, Annie Kilroy, Erica Colston, Vanessa Lizcano, Erin Eggleston, Iasmin Goes, Oliver Babcock, Raheem Chaudhry, Daniel Chapman, Garrett Shuffield, Akshat Gautam, Abby Brown, Delainey Peterson, Eduardo Velasquez, Evelin Caro, Jonathan Velasquez, Alex

Walheim, Amanda Long, Haley McCoin, Maria Fernanda Guerrero, Jake Barnet, Tawheeda Wahabzada, Bianca Remmie, Anna Scanlon, Alejandra Gaytan, Vishal Duvuuru, Jennifer Johnson, Sam Gorme, Miles Hudson, Sarah Fischer, Vivianna Brown, Leah Havens, Daniela Garcia, Jennifer McGinty, Chris Zimmer, Lizzette Marrero, Nathalia Rojas, Josh Hamlin, Maren Taylor, Kristle Hinola, Johnny Shaw, Regan Seckel, Kiara Hays, Kolby Vidrine, Katherine Donovan, Kate Adams, Anita Basavaraju, Arijit Paladhi, Arvind Ashok, Brandon Gajeton, Carlos Diaz, Destiny Alvarez, Domingo Salerno, Drew Burd, Hannah Greer, Raven Langhorne, Jade Tucker, Tyler Morrow, Ji Na Gil, Kanika Varma, Karan Kanatala, Kimberly Schuster, Levi Malloy, Lila Al-Kassem, Mackenna Shull, Mariana Caldas, Patrick Golden, Samiya Javed, Michael Hankins, Justin Ahamed, Sam Bennett, Skyler Thomas, Andrew Butemeyer, Samantha Shoff, Beomhak Lee, Benjamin Vega, Mobin Piracha, Ashley Frey, Rama Singh Rastogi, Adityamohan Tantravahi, Jake Reynolds, Kelvin Efiya, JP Repetto, Nick Romanov, Nikola Skerl, Keeton Schenck, and Ethan Masucol. At the University of North Carolina at Charlotte, Megan Bird and Nathan Duma contributed to the data collection as well.
